

Intrinsic disorder is enriched in alternatively-spliced exons

a, Pooled χ^2 test of independence (2x2: exon type x IDR status, df = 1) per cohort; IDR status = `idr_frac` $\geq$ 0.5, OR = (alt IDR odds)/(const IDR odds). b, Per-gene difference in IDR fraction (alternative – constitutive) — a bounded, small-sample-stable effect size; % of genes with $\Delta > 0$ and a binomial sign-test. c, Per-gene volcano: $\log_2(\text{OR})$ vs $-\log_{10}(\text{Fisher } P)$, one dot per gene (≥ 4 classifiable exons). Significance: * $P < 0.05$, ** $P < 0.01$, *** $P < 0.001$.
