

Alternative splicing leaves most IDR exons intact; removal exceeds addition — equally in TFs and non-TFs

conserved (in both) removed (canonical only) added (alternative only)

TF vs non-TF fate distribution: χ^2 test on 2×3 (TF/non-TF × conserved/removed/added): $P = 0.75$ (n.s.), Cramér's $V = 0.004$ (negligible).
