

Alternative-exon disorder diverges over evolution: TFs rise, non-TFs fall (fig16 metric)

Continuous per-exon idr_frac (fig16), unique alternative exons (dedup gene+exon_id). Solid=median, dashed=quartiles, grey dashed line = IDR-exon cutoff (0.5); distribution is bimodal (0 or 1) so means/trend lines carry the shift. ns $p \geq 0.05$ **** $p < 0.0001$
